FEAT U R E S
Complete 14-Bit Voltage Output DAC
Parallel and Serial Interface Capability
80 dB Signal-to-Noise Ratio
Interfaces to High Speed DSP Processors
e.g., ADSP-2100, TMS32010, TMS32020
45 ns min WR Pulse Width
Low Power - 70 mW typ.
Operates from ±5 V Supplies

F U N C T I O N A L  B L O C K  D I A G R A M

G E N E R A L  D E S C R I P T I O N
The AD7840 is a fast, complete 14-bit voltage output D/A converter. It consists of a 14-bit D/A, 3 V buried Zener reference, D/A output amplifier and high speed control logic.

The part features double-buffered interface logic with a 14-bit input latch and 14-bit D/A latch. Data is loaded to the input latch in either of two modes, parallel or serial. This data is then transferred to the DAC latch under control of an asynchronous LDAC signal. A fast data setup time of 21 ns allows direct parallel interfacing to digital signal processors and high speed 16-bit microprocessors. In the serial mode, the maximum serial data clock rate can be as high as 6 MHz.

The analog output from the AD7840 provides a bipolar output range of ±3 V. The AD7840 is fully specified for dynamic performance parameters such as signal-to-noise ratio and harmonic distortion as well as for traditional dc specifications. Full power output signals up to 20 kHz can be created.

The AD7840 is fabricated in linear compatible CMOS (LC²MOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The part is available in a 24-pin plastic and hermetic dual-in-line package (DIP) and is also packaged in a 28-terminal plastic leaded chip carrier (PLCC).

P R O D U C T  H I G H L I G H T S
1. Complete 14-Bit D/A Function
   The AD7840 provides the complete function for creating ac signals and dc voltages to 14-bit accuracy. The part features an on-chip reference, an output buffer amplifier and 14-bit D/A converter.

2. Dynamic Specifications for DSP Users
   In addition to traditional dc specifications, the AD7840 is specified for ac parameters including signal-to-noise ratio and harmonic distortion. These parameters along with important timing parameters are tested on every device.

3. Fast, Versatile Microprocessor Interface
   The AD7840 is capable of 14-bit parallel and serial interfacing. In the parallel mode, data setup times of 21 ns and write pulse widths of 45 ns make the AD7840 compatible with modern 16-bit microprocessors and digital signal processors. In the serial mode, the part features a high data transfer rate of 6 MHz.

- Lead Temperature (Soldering, 10 sec): \(+300\,\text{C}\)
- Power Dissipation (Any Package) to \(+75\,\text{C}\): \(450\,\text{mW}\)
- Derates above \(+75\,\text{C}\) by: \(10\,\text{mW/}^\circ\text{C}\)

*Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**CAUTION**

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as \(4000\,\text{V}\) readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7840 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

* = DON'T CARE
D/A SECTION
The AD7840 contains a 14-bit voltage mode D/A converter consisting of highly stable thin film resistors and high speed NMOS single-pole, double-throw switches. The simplified circuit diagram for the DAC section is shown in Figure 1. The three MSBs of the data word are decoded to drive the seven switches A–G. The 11 LSBs switch an 11-bit R-2R ladder structure. The output voltage from this converter has the same polarity as the reference voltage, REF IN.

The REF IN voltage is internally buffered by a unity gain amplifier before being applied to the D/A converter and the bipolar bias circuitry. The D/A converter is configured and sealed for a 3 V reference and the device is tested with 3 V applied to REF IN. Operating the AD7840 at reference voltages outside the ±5% tolerance range may result in degraded performance from the part.

EXTERNAL REFERENCE
In some applications, the user may require a system reference or some other external reference to drive the AD7840 reference input. Figure 3 shows how the AD586 5 V reference can be conditioned to provide the 3 V reference required by the AD7840 REF IN. An alternate source of reference voltage for the AD7840 in systems which use both a DAC and an ADC is to use the REF OUT voltage of ADCs such as the AD7870 and AD7871. A circuit showing this arrangement is shown in Figure 20.

INTERNAL REFERENCE
The AD7840 has an on-chip temperature compensated buried Zener reference (see Figure 2) which is factory trimmed to 3 V ±10 mV. The reference voltage is provided at the REF OUT pin. This reference can be used to provide both the reference voltage for the D/A converter and the bipolar bias circuitry. This is achieved by connecting the REF OUT pin to the REF IN pin of the device.

The reference voltage can also be used as a reference for other components and is capable of providing up to 500 µA to an external load. The maximum recommended capacitance on REF OUT for normal operation is 50 pF. If the reference is required for external use, it should be decoupled to AGND with a 200 Ω resistor in series with a parallel combination of a 10 µF tantalum capacitor and a 0.1 µF ceramic capacitor.
The output from the voltage mode DAC is buffered by a
noninverting amplifier. Internal scaling resistors on the AD7840
configure an output voltage range of ±3 V for an input reference
voltage of +3 V. The arrangement of these resistors around the
output op amp is as shown in Figure 1. The buffer amplifier is
capable of developing ±3 V across a 2 kΩ and 100 pF load to
ground and can produce 6 V peak-to-peak sine wave signals to a
frequency of 20 kHz. The output is updated on the falling edge
of the LDAC input. The amplifier settles to within 1/2 LSB of
its final value in typically less than 2.5 µs.

The small signal (200 mV p-p) bandwidth of the output buffer
amplifier is typically 1 MHz. The output noise from the ampli-
fier is low with a figure of 30 nV/√Hz at a frequency of 1 kHz.
Figure 4 shows a typical plot of noise spectral density versus frequency
for the output buffer amplifier and for the on-chip reference.

The output voltage can be expressed in terms of the input code,
N, using the following expression:

\[ V_{OUT} = \frac{2 \times N \times \text{REFIN}}{16384} - 8192 \leq N \leq +8191 \]

The output voltage can be expressed in terms of the input code,
N, using the following expression:

\[ V_{OUT} = \frac{2 \times N \times \text{REFIN}}{16384} - 8192 \leq N \leq +8191 \]

**TRANSFER FUNCTION**

The basic circuit configuration for the AD7840 is shown in Figure 5. Table II shows the ideal input code to output voltage re-
relationship for this configuration. Input coding to the DAC is 2s
complement with 1 LSB = FS/16,384 = 6 V/16,384 = 366 µV.

**INTERFACE LOGIC INFORMATION**

The AD7840 contains two 14-bit latches, an input latch and a
DAC latch. Data can be loaded to the input latch in one of two
basic interface formats. The first is a parallel 14-bit wide data
word; the second is a serial interface where 16 bits of data are
serially clocked into the input latch. In the parallel mode, CS
and WR control the loading of data. When the serial data format
is selected, data is loaded using the SCLK, SYNC and SDATA
serial inputs. Data is transferred from the input latch to the
DAC latch under control of the LDAC signal. Only the data in
the DAC latch determines the analog output of the AD7840.

**Parallel Data Format**

Table III shows the truth table for AD7840 parallel mode op-
eration. The AD7840 normally operates with a parallel input
data format. In this case, all 14 bits of data (appearing on data
inputs D13 (MSB) through D0 (LSB)) are loaded to the
AD7840 input latch at the same time. CS and WR control the
loading of this data. These control signals are level-triggered;
therefore, the input latch can be made transparent by holding
both signals at a logic low level. Input data is latched into the in-
put latch on the rising edge of CS or WR.

The DAC latch is also level triggered. The DAC output is nor-
maledly updated on the falling edge of the LDAC signal. How-
ever, both latches cannot become transparent at the same time.
Therefore, if LDAC is hardwired low, the part operates as fol-
lows: with LDAC low and CS and WR high, the DAC latch is
transparent. When CS and WR go low (with LDAC still low),
the input latch becomes transparent but the DAC latch is dis-
able. When CS or WR return high, the input latch is locked
out and the DAC latch becomes transparent again and the DAC
output is updated. The write cycle timing diagram for parallel
data is shown in Figure 6. Figure 7 shows the simplified parallel
input control logic for the AD7840.

Serial Data Format

The serial data format is selected for the AD7840 by connecting the CS/SERIAL line to -5 V. In this case, the WR/SYNC, D13/SDATA, D12/SCLK, D11/FORMAT and D10/JUSTIFY pins all assume their serial functions. The unused parallel inputs should not be left unconnected to avoid noise pickup. Serial data is loaded to the input latch under control of SCLK, SYNC and SDATA. The AD7840 expects a 16-bit stream of serial data on its SDATA input. Serial data must be valid on the falling edge of SCLK. The SYNC input provides the frame synchronization signal which tells the AD7840 that valid serial data will be available for the next 16 falling edges of SCLK. Figure 8 shows the timing diagram for serial data format.

Although 16 bits of data are clocked into the AD7840, only 14 bits go into the input latch. Therefore, two bits in the stream are don’t cares since their value does not affect the input latch data. The order and position in which the AD7840 accepts the 14 bits of input data depends upon the FORMAT and JUSTIFY inputs. There are four different input data modes which can be chosen (see Table I in the Pin Function Description section).

The first mode (M1) assumes that the first two bits of the input data stream are don’t cares, the third bit is the LSB and the last (or 16th bit) is the MSB. This mode is chosen by tying both the FORMAT and JUSTIFY pins to a logic 0. The second mode (M2; FORMAT = 0, JUSTIFY = 1) assumes that the first bit in the data stream is the LSB, the fourteenth bit is the MSB and the last two bits are don’t cares. The third mode (M3; FORMAT = 1, JUSTIFY 0) assumes that the first two bits in the stream are again don’t cares, the third bit is now the MSB and the sixteenth bit is the LSB. The final mode (M4; FORMAT = 1, JUSTIFY = 1) assumes that the first bit is the MSB, the fourteenth bit is the LSB and the last two bits of the stream are don’t cares.
As in the parallel mode, the LDAC signal controls the loading of data to the DAC latch. Normally, data is loaded to the DAC latch on the falling edge of LDAC. However, if LDAC is held low, then serial data is loaded to the DAC latch on the sixteenth falling edge of SCLK. If LDAC goes low during the transfer of serial data to the input latch, no DAC latch update takes place on the falling edge of LDAC. If LDAC stays low until the serial transfer is completed, then the update takes place on the sixteenth falling edge of SCLK. If LDAC returns high before the serial data transfer is completed, no DAC latch update takes place. Figure 9 shows the simplified serial input control logic for the AD7840.

![Figure 9. AD7840 Simplified Serial Input Control Logic](image)

**AD7840 DYNAMIC SPECIFICATIONS**

The AD7840 is specified and 100% tested for dynamic performance specifications as well as traditional dc specifications such as integral and differential nonlinearity. These ac specifications are required for the signal processing applications such as speech synthesis, servo control and high speed modems. These applications require information on the DAC’s effect on the spectral content of the signal it is creating. Hence, the parameters for which the AD7840 is specified include signal-to-noise ratio, harmonic distortion and peak harmonics. These terms are discussed in more detail in the following sections.

**Signal-to-Noise Ratio (SNR)**

SNR is the measured signal-to-noise ratio at the output of the DAC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency (fs/2) excluding dc. SNR is dependent upon the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to noise ratio for a sine wave output is given by

\[ \text{SNR} = (6.02N + 1.76) \text{ dB} \]  

where \( N \) is the number of bits. Thus for an ideal 14-bit converter, \( \text{SNR} = 86 \text{ dB} \).

Figure 10 shows a typical 2048 point Fast Fourier Transform (FFT) plot of the AD7840KN with an output frequency of 1 kHz and an update rate of 100 kHz. The SNR obtained from this graph is 81.8 dB. It should be noted that the harmonics are taken into account when calculating the SNR.

![Figure 10. AD7840 FFT Plot](image)

**Effective Number of Bits**

The formula given in (1) relates the SNR to the number of bits. Rewriting the formula, as in (2) it is possible to get a measure of performance expressed in effective number of bits (N).

\[ N = \frac{\text{SNR} - 1.76}{6.02} \]  

The effective number of bits for a device can be calculated directly from its measured SNR.

**Harmonic Distortion**

Harmonic distortion is the ratio of the rms sum of harmonics to the fundamental. For the AD7840, total harmonic distortion (THD) is defined as

\[ \text{THD} = 20 \log \sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2} \] 

where \( V_1 \) is the rms amplitude of the fundamental and \( V_2, V_3, V_4, V_5 \) and \( V_6 \) are the rms amplitudes of the second through the sixth harmonic. The THD is also derived from the 2048-point FFT plot.

**Peak Harmonic or Spurious Noise**

Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the DAC output spectrum (up to fs/2 and excluding dc) to the rms value of the fundamental. Normally, the value of this specification will be determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor the peak will be a noise peak.

**Testing the AD7840**

A simplified diagram of the method used to test the dynamic performance specifications is outlined in Figure 11. Data is loaded to the AD7840 under control of the microcontroller and associated logic at a 100 kHz update rate. The output of the AD7840 is applied to a ninth order, 50 kHz, low-pass filter. The output of the filter is in turn applied to a 16-bit accurate digitizer. This digitizes the signal and the microcontroller generates an FFT plot from which the dynamic performance of the AD7840 can be evaluated.
Figure 11. AD7840 Dynamic Performance Test Circuit

The digitizer sampling is synchronized with the AD7840 update rate to ease FFT calculations. The digitizer samples the AD7840 after the output has settled to its new value. Therefore, if the digitizer was to sample the output directly it would effectively be sampling a dc value each time. As a result, the dynamic performance of the AD7840 would not be measured correctly. Using the digitizer directly on the AD7840 output would give better results than the actual performance of the AD7840. Using a filter between the DAC and the digitizer means that the digitizer samples a continuously moving signal and the true dynamic performance of the AD7840 is measured.

Some applications will require improved performance versus frequency from the AD7840. In these applications, a simple sample-and-hold circuit such as that outlined in Figure 12 will extend the very good performance of the AD7840 to 20 kHz.

Figure 12. Sample-and-Hold Circuit

Other applications will already have an inherent sample-and-hold function following the AD7840. An example of this type of application is driving a switched-capacitor filter where the updating of the DAC is synchronized with the switched-capacitor filter. This inherent sample-and-hold function also extends the frequency range performance of the AD7840.

Performance versus Frequency

The typical performance plots of Figures 13 and 14 show the AD7840's performance over a wide range of input frequencies at an update rate of 100 kHz. The plot of Figure 13 is without a sample-and-hold on the AD7840 output while the plot of Figure 14 is generated with the sample-and-hold circuit of Figure 12 on the output.

Figure 13. Performance vs. Frequency (No Sample-and-Hold)

Figure 14. Performance vs. Frequency (with Sample-and-Hold)
MICROPROCESSOR INTERFACEING

The AD7840 logic architecture allows two interfacing options for interfacing the part to microprocessor systems. It offers a 14-bit wide parallel format and a serial format. Fast pulse widths and data setup times allow the AD7840 to interface directly to most microprocessors including the DSP processors. Suitable interfaces to various microprocessors are shown in Figures 15 to 23.

**Parallel Interfacing**

Figures 15 to 17 show interfaces to the DSP processors, the ADSP-2100, the TMS32010 and TMS32020. An external timer controls the updating of the AD7840. Data is loaded to the AD7840 input latch using the following instructions:

- **ADSP-2100:** `DM(DAC) = MR0`
- **TMS32010:** `OUT DAC,D`
- **TMS32020:** `OUT DAC,D`

Where:

- `DAC` = AD7840 Address
- `MR0` = ADSP-2100 MR0 Register
- `D` = Data Memory Address

Some applications may require that the updating of the AD7840 DAC latch be controlled by the microprocessor rather than the external timer. One option (for double-buffered interfacing) is to decode the AD7840 LDAC from the address bus so that a write operation to the DAC latch (at a separate address than the input latch) updates the output. An example of this is shown in the 8086 interface of Figure 18. Note that connecting the LDAC input to the CS input will not load the DAC latch correctly since both latches cannot be transparent at the same time.

**AD7840-8086 Interface**

Figure 18 shows an interface between the AD7840 and the 8086 microprocessor. For this interface, the LDAC input is derived from a decoded address. If the least significant address line, A0, is decoded then the input latch and the DAC latch can reside at consecutive addresses. A move instruction loads the input latch while a second move instruction updates the DAC latch and the AD7840 output. The move instruction to load a data wordWXYZ to the input latch is as follows:

`MOV DAC,#WXYZ`

Where:

- `DAC` = AD7840 Address
AD7840–68000 Interface

An interface between the AD7840 and the 68000 microprocessor is shown in Figure 19. In this interface example, the LDAC input is hardwired low. As a result the DAC latch and analog output are updated on the rising edge of WR. A single move instruction, therefore, loads the input latch and updates the output.

```
MOVE.W D0, $DAC
D0 = 68000 D0 Register
DAC = AD7840 Address
```

Figure 19. AD7840–MC68000 Parallel Interface

Serial Interfacing

Figures 20 to 23 show the AD7840 configured for serial interfacing with the CS input hardwired to -5 V. The parallel bus is not activated during serial communication with the AD7840.

AD7840–ADSP-2101/ADSP-2102 Serial Interface

Figure 20 shows a serial interface between the AD7840 and the ADSP-2101/ADSP-2102 DSP processor. Also included in the interface is the AD7870, a 12-bit A/D converter. An interface such as this is suitable for modem and other applications which have a DAC and an ADC in serial communication with a microprocessor.

The interface uses just one of the two serial ports of the ADSP-2101/ADSP-2102. Conversion is initiated on the AD7870 at a fixed sample rate (e.g., 9.6 kHz) which is provided by a timer or clock recovery circuitry. While communication takes place between the ADC and the ADSP-2101/ADSP-2102, the AD7870 SSTRB line is low. This SSTRB line is used to provide a frame synchronization pulse for the AD7840 SYNC and ADSP-2101/ADSP-2102 TFS lines. This means that communication between the processor and the AD7840 can only take place while the AD7870 is communicating with the processor. This arrangement is desirable in systems such as modems where the DAC and ADC communication should be synchronous.

The use of the AD7870 SCLK for the AD7840 SCLK and ADSP-2101/ADSP-2102 SCLK means that only one serial port of the processor is used. The serial clock for the AD7870 must be set for continuous clock for correct operation of this interface. Data from the ADSP-2101/ADSP-2102 is valid on the falling edge of SCLK. The LDAC input of the AD7840 is permanently low so the update of the DAC latch and analog output takes place on the sixteenth falling edge of SCLK (with SYNC low). The FORMAT pin of the AD7840 must be tied to +5 V and the JUSTIFY pin tied to DGND for this interface to operate correctly.

Figure 20. Complete DAC/ADC Serial Interface

AD7840–DSP56000 Serial Interface

A serial interface between the AD7840 and the DSP56000 is shown in Figure 21. The DSP56000 is configured for normal mode synchronous operation with gated clock. It is also set up for a 16-bit word with SCK and SC2 as outputs and the FSL control bit set to a 0. SCK is internally generated on the DSP56000 and applied to the AD7840 SCLK input. Data from the DSP56000 is valid on the falling edge of SCK. The SC2 output provides the framing pulse for valid data. This line must be inverted before being applied to the SYNC input of the AD7840.

The LDAC input of the AD7840 is connected to DGND so the update of the DAC latch takes place on the sixteenth falling edge of SCLK. As with the previous interface, the FORMAT pin of the AD7840 must be tied to +5 V and the JUSTIFY pin tied to DGND.

Figure 21. AD7840–DSP56000 Serial Interface
AD7840

AD7840-TM S32020 Serial Interface
Figure 22 shows a serial interface between the AD7840 and the TMS32020 DSP processor. In this interface, the CLKX and FSX pin of the TMS32020 are generated from the clock/timer circuitry. The same clock/timer circuitry generates the LDAC signal of the AD7840 to synchronize the update of the output with the serial transmission. The FSX pin of the TMS32020 must be configured as an input. Data from the TMS32020 is valid on the falling edge of CLKX. Once again, the FORMAT pin of the AD7840 must be tied to +5 V while the JUSTIFY pin must be tied to DGND.

AD7840–NEC7720 Serial Interface
A serial interface between the AD7840 and the NEC7720 is shown in Figure 23. The serial clock must be inverted before being applied to the AD7840 SCLK input because data from the processor is valid on the rising edge of SCK. The NEC7720 is programmed for the LSB to be the first bit in the serial data stream. Therefore, the AD7840 is set up with the FORMAT pin tied to DGND and the JUSTIFY pin tied to +5 V.

Figure 24. Power Supply Grounding Practice
Low impedance analog and digital power supply return tracks are essential to low noise operation of high performance converters. Therefore, the foil width for these tracks should be kept as wide as possible. The use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise. The circuit layouts of Figures 27 and 28 have both analog and digital ground planes which are kept separated and only joined at the star ground close to the AD7840.

NOISE
Keep the signal leads on the VOUT signal and the signal return leads to AGND as short as possible to minimize noise coupling. In applications where this is not possible, use a shielded cable between the DAC output and its destination. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the DAC and its destination device appears as an error voltage in series with the DAC output.

APPLYING THE AD7840
Good printed circuit board layout is as important as the overall circuit design itself in achieving high speed converter performance. The AD7840 works on an LSB size of 366 µV. Therefore, the designer must be conscious of minimizing noise in both the converter itself and in the surrounding circuitry. Switching mode power supplies are not recommended as the switching spikes can feed through to the on-chip amplifier. Other causes of concern are ground loops and digital feedthrough from microprocessors. These are factors which influence any high performance converter, and a proper PCB layout which minimizes these effects is essential for best performance.

LAYOUT HINTS
Ensure that the layout for the printed circuit board has the digital and analog lines separated as much as possible. Take care not to run any digital track alongside an analog signal track. Establish a single point analog ground (star ground) separate from the logic system ground. Place this star ground as close as possible to the AD7840 as shown in Figure 24. Connect all analog grounds to this star ground and also connect the AD7840 DGND pin to this ground. Do not connect any other digital grounds to this analog ground point.
DATA ACQUISITION BOARD
Figure 25 shows the AD7840 in a data acquisition circuit. The corresponding printed circuit board (PCB) layout and silkscreen are shown in Figures 26 to 28. The board layout has three interface ports: one serial and two parallel. One of the parallel ports is directly compatible with the ADSP-2100 evaluation board expansion connector.

Some systems will require the addition of a reconstruction filter on the output of the AD7840 to complete the data acquisition system. There is a component grid provided near the analog output on the PCB which may be used for such a filter or any other output conditioning circuitry. To facilitate this option, there is a shorting plug (labeled LK1 on the PCB) on the analog output track. If this shorting plug is used, the analog output connects to the output of the AD7840; otherwise this shorting plug can be omitted and a wire link used to connect the analog output to the PCB component grid.

The board also contains a simple sample-and-hold circuit which can be used on the output of the AD7840 to extend the very good performance of the AD7840 over a wider frequency range. A second wire link (labeled LK2 on the PCB) connects VOUT (SKT1) to either the output of this sample-and-hold circuit or directly to the output of the AD7840.

INTERFACE CONNECTIONS
There are two parallel connectors, labeled SKT4 and SKT6, and one serial connector, labeled SKT5. A shorting plug option (LK8 in Figure 25) on the AD7840 CS/serial interface configures the DAC for the appropriate interface (see Pin Function Description).

SKT6 is a 96-contact (3-row) Eurocard connector which is directly compatible with the ADSP-2100 Evaluation Board Prototype Expansion Connector. The expansion connector on the ADSP-2100 has eight decoded chip enable outputs labeled ECE1 to ECE8. ECE8 is used to drive the AD7840 CS input on the data acquisition board. To avoid selecting on-board sockets at the same time, LK6 on the ADSP-2100 board must be removed. The AD7840 and ADSP-2100 data lines are aligned for left justified data transfer.

SKT4 is a 26-way (2-row) IDC connector. This connector contains the same signal contacts as SKT6 and in addition contains decoded R/W and STRB inputs which are necessary for TMS32020 interfacing. This decoded WR can be selected via LK4. The pinout for this connector is shown in Figure 29.

SKT5 is a nine-way D-type connector which is meant for serial interfacing only. The evaluation board has the facility to invert SYNC line via LK7. This is necessary for serial interfacing between the AD7840 and DSP processors such as the DSP56000. The SKT5 pinout is shown in Figure 30.

SKT1, SKT2 and SKT3 are three BNC connectors which provide connections for the analog output, the LDAC input and an external reference input. The use of an external reference is optional: the shorting plug (LK3) connects the REF IN pin to either this external reference or to the AD7840’s own internal reference.

Wire links LK5 and LK6 connect the D11 and D10 inputs to the data lines for parallel operation. In the serial mode, these links allow the user to select the required format and justification for serial data (see Table I).

POWER SUPPLY CONNECTIONS
The PCB requires two analog power supplies and one 5 V digital supply. Connections to the analog supplies are made directly to the PCB as shown on the silkscreen in Figure 26. The connections are labelled V+ and V– and the range for both of these supplies is 12 V to 15 V. Connection to the 5 V digital supply is made through any of the connectors (SKT4 to SKT6). The −5 V analog supply required by the AD7840 is generated from a voltage regulator on the V– power supply input (IC5 in Figure 25).

SHORTING PLUG OPTIONS
There are eight shorting plug options which must be set before using the board. These are outlined below:

LK1 Connects the analog output to SKT1. The analog output may also be connected to a component grid for signal conditioning.
LK2 Selects either the AD7840 VOUT or the sample-and-hold output.
LK3 Selects either the internal or external reference.
LK4 Selects the decoded R/W and STRB inputs for TMS32020 interfacing.
LK5 Configures the D11/FORMAT input.
LK6 Configures the D10/JUSTIFY input.
LK7 Selects either the inverted or noninverted SYNC.
LK8 Selects either parallel or serial interfacing.
